ELEC6021 — COMMS Assignment I

- Complete the set of simulations as indicated in Assignment I
- Hand in your assignment to the ECS Student Services (no longer called Course Office) on ——
- Mark contribution to the unit: 25% (Total 25 marks)
- A few "hints" are given in this lecture
- Assignment and this lecture notes can be downloaded from

http://www.ecs.soton.ac.uk/~sqc/EZ619/

• There will be no lecture for 2nd lecture time slot – use it for you to do this assignment

Simulation of Carrier Communication Systems

- In Assignment, we are going to simulate carrier communication systems
- A simple way of representing a continuous-time signal is to use a discrete-time signal obtained by fast sampling
- Thus for carrier of f_c we may need a sampling rate, say, approximately $10 \times f_c$, but in real world carrier frequencies are in GHz
- What is the carrier frequency we will be used in our simulation? Why could we use a more realistic carrier, say 1 GHz, in simulation?
- Since we use sampled discrete-time signal to represent continuous-time signal, we must first know it is OK to do so
- Intuitively, if we sample very fast the sampled signal will look like the original continuous-time signal, but of course it is more than that

Normalisation

- Many Matlab functions such as those for filter design prefer normalised frequency parameters, and such normalisations are with respect to the sampling rate
- Therefore, if f and f_s are the absolute frequency and absolute sampling rate, the f_{norm} and $f_{s,norm}$ are the relative, normalised parameters, which have to fulfill

$$\frac{f}{f_{\rm s}} = \frac{f_{\rm norm}}{f_{\rm s,norm}} \tag{1}$$

Therefore

$$f_{\rm norm} = f_{\rm s,norm} \cdot \frac{f}{f_{\rm s}} = 2 \cdot \frac{f}{f_{\rm s}}$$
 (2)

whereby $f_{s,norm} = 2$ has been inserted as normalised sampling rate (see e.g. help fir1 or help psd to check this)

• What this means: Frequency $f = \frac{f_s}{2}$ is normalised as $f_{norm} = 1$

What Happens When Sampling

 (a) the true spectrum X(f) of a continuous-time signal x(t), and (b) the spectrum X(f) of the sampled signal x[k] = x_s(t) at a sampling rate f_s

 $X_s(f)$ is periodic with a period f_s , and we only need a period of $X_s(f)$ to represent it. Also distortion occurred around $\frac{f_s}{2}$ (unless X(f) is bandlimited with a bandwidth less than or equal to $\frac{f_s}{2}$)

• In fact we only need to show $X_s(f)$ from f=0 to $f=\frac{f_s}{2}$

Written Assignment

- No point to display the spectrum of a sampled signal beyond $f = \frac{f_s}{2} \rightarrow$ those are "artifacts" due to sampling operation
- Only the spectrum within f = 0 to $f = \frac{f_s}{2}$ is relevant to the original spectrum of the continuous-time signal

That is, the spectrum in frequency range 0 to 1 (recall $f = \frac{f_s}{2}$ corresponds to $f_{\text{norm}} = 1$)

• Written assignment should be **concise** and contains a set of **clearly labelled figures**

Do not forget **units**, unless for normalised quantities

 Overall system gain should be kept to unity, otherwise you may have "unexpected" results

Example of Written Assignment

1 AM/FM Analogue Modulation

1.1 AM Modulation

The required lowpass filter can be constructed according to $f_{\text{cutoff,norm}} = 2 \cdot 10 \text{ kHz}/2 \text{ MHz} = 0.01$; the resulting PSD of the signal after filtering x(t):
