B-Spline Neural Network Based Single-Carrier Frequency Domain Equalisation for Hammerstein Channels

Xia Hong, Sheng Chen and Chris J. Harris

Abstract—A practical single-carrier (SC) block transmission with frequency domain equalisation (FDE) system can generally be modelled by the Hammerstein system that includes the nonlinear distortion effects of the high power amplifier (HPA) at transmitter. For such Hammerstein channels, the standard SC-FDE scheme no longer works. We propose a novel B-spline neural network based nonlinear SC-FDE scheme for Hammerstein channels. In particular, we model the nonlinear HPA, which represents the complex-valued static nonlinearity of the Hammerstein channel, by two real-valued B-spline neural networks, one for modelling the nonlinear amplitude response of the HPA and the other for the nonlinear phase response of the HPA. We then develop an efficient alternating least squares algorithm for estimating the parameters of the Hammerstein channel, including the channel impulse response coefficients and the parameters of the two B-spline models. Moreover, we also use another real-valued B-spline neural network to model the inversion of the HPA’s nonlinear amplitude response, and the parameters of this inverting B-spline model can be estimated using the standard least squares algorithm based on the pseudo training data obtained as a byproduct of the Hammerstein channel identification. Equalisation of the SC Hammerstein channel can then be accomplished by the usual one-tap linear equalisation in frequency domain as well as the inverse B-spline neural network model obtained in time domain. The effectiveness of our nonlinear SC-FDE scheme for Hammerstein channels is demonstrated in a simulation study.

I. INTRODUCTION

The fourth generation (4G) and beyond 4G (B4G) mobile communication systems support high-speed broadband applications with data rates in tens of Mbps or higher over the wireless channel of typical delay spread in microseconds. The intersymbol interference (ISI) of such wireless channels spans over tens or even hundreds of symbols, which causes the nightmare scenario for time-domain (TD) equalisation, requiring an impractically long equaliser with excessively slow convergence and therefore resulting in poor performance. Orthogonal frequency-division multiplexing (OFDM) [1], [2] offers a low-complexity high-performance solution for mitigating long ISI. Owing to its virtues of resilience to frequency selective fading channels, OFDM has found its way into numerous recent wireless network standards. However, an OFDM signal is notoriously known to have high peak-to-average power ratio (PAPR), which requires the high power amplifier (HPA) at the transmitter to have an extremely long linear dynamic range. This requirement may not be met by practical HPAs which exhibits nonlinear saturation characteristics [3]–[7]. An alternative solution for long ISI mitigation is to adopt single-carrier (SC) block transmission with frequency-domain equalisation (FDE) [8], [9]. Although the total complexity of a SC-FDE based transceiver is the same as that of an OFDM based transceiver, the SC-FDE transmitter does not require the fast Fourier transform (FFT) operation, and therefore it is better suited for uplink implementation. The long term evolution advanced (LTE-A) has specified the standard for the uplink of the 4G and B4G systems based on the SC-FDE solution [10].

In order to enhance the achievable bandwidth efficiency, SC based broadband systems typically adopt high-order quadrature amplitude modulation (QAM) signalling [11]. The higher the order of QAM signalling, the better the bandwidth efficiency but also the higher the PAPR of the resulting transmit signal. This may drive the HPA at the transmitter into the nonlinear saturation region, which will significantly degrade the system’s achievable bit error rate (BER) performance. Therefore, it is important to be able to effectively compensate the nonlinear distortions of the HPA in the design of a SC based high-rate wireless system. An effective approach to compensate the nonlinear distortions of HPA is to implement a digital predistorter at the transmitter, which is capable of achieving excellent performance, and various predistorter techniques have been developed [12]–[18]. Implementing the predistorter is attractive for the downlink, where the base station (BS) transmitter has the sufficient hardware and software capacities to accommodate the hardware and computational requirements for implementing digital predistorter. In the uplink, however, implementing predistorter at transmitter is much more difficult, as it is extremely challenging for a pocket-size handset to absorb the additional hardware and computational complexity. Therefore, the predistorter option is not viable for the SC-FDE based uplink. Alternatively, the nonlinear distortions of the transmitter HPA can be dealt with at the BS receiver, which has sufficient hardware and software resources. With the nonlinear HPA at transmitter, the channel is a complex-valued (CV) Hammerstein system and, moreover, the received signal is further impaired by the channel additive white Gaussian noise (AWGN). Therefore, nonlinear equalisation of the SC based Hammerstein channel is a challenging task.

In this contribution, we propose an efficient nonlinear SC-FDE scheme for Hammerstein channels based on the B-spline neural network. In our previous works [18], [19], the B-spline neural network has been demonstrated to be very effective in identification and inversion of CV Wiener...
systems. We adopt two real-valued (RV) B-spline neural networks to model the amplitude response and the phase response of the CV static nonlinearity of the Hammerstein channel, and we develop a highly efficient alternating least squares (ALS) identification algorithm for estimating the channel impulse response (CIR) coefficients as well as the parameters of the two RV B-spline neural networks that model the HPA’s CV static nonlinearity. As linear equalisation is naturally accomplished in SC-FDE based systems by a one-tap equalisation in frequency domain (FD), nonlinear SC-FDE of the Hammerstein channel additionally involves the inversion of the estimated B-spline neural network that models the HPA’s nonlinear amplitude response in TD, as the compensation of the HPA’s nonlinear phase response is straightforward using the estimated phase response. The previous work [18] considers the inversion of a RV B-spline model as the root finding problem, and develop an iterative root finding procedure based on the Gauss-Newton algorithm for inverting the estimated amplitude response. This approach requires to carry out the iterative root finding procedure for detecting every data symbol. We propose a much faster and more efficient alternative for inverting the HPA’s nonlinear amplitude response. Specifically, we use another RV B-spline neural network to model the inversion of the HPA’s nonlinear amplitude response. Although the HPA’s output at the transmitter is unobservable at the receiver for identifying this inverse model, the pseudo training data obtained as a natural byproduct of the Hammerstein channel identification can be used to estimate the parameters of the inverting B-spline model using the standard least squares (LS) algorithm. We demonstrate the effectiveness of our proposed B-spline neural network based SC-FDE scheme for Hammerstein channels in an extensive simulation study.

Throughout this contribution, a CV number $x \in \mathbb{C}$ is represented either by the rectangular form $x = x_R + j x_I$, where $j = \sqrt{-1}$, while $x_R = \Re\{x\}$ and $x_I = \Im\{x\}$ denote the real and imaginary parts of $x$, or alternatively by the polar form $x = |x| \cdot e^{j \phi x}$ with $|x|$ denoting the amplitude of $x$ and $\phi x$ its phase. The vector or matrix transpose and conjugate transpose operators are denoted by $(\cdot)^T$ and $(\cdot)^H$, respectively, while $(\cdot)^{-1}$ stands for the inverse operation and the expectation operator is denoted by $E\{\}$. Furthermore, $I$ denotes the identity matrix with an appropriate dimension, and $\text{diag}\{x_0, x_1, \ldots, x_{N-1}\}$ is the diagonal matrix with $x_0, x_1, \ldots, x_{N-1}$ as its diagonal elements.

II. HAMMERSTEIN CHANNEL MODEL FOR SC-FDE

We consider the $M$-QAM signalling. Each transmit block or frame consists of $N$ QAM data symbols expressed as

$$x[s] = [x_0[s] \ x_1[s] \ \cdots \ x_{N-1}[s]]^T,$$  

where $[s]$ denotes the block index, and $x_k[s], 0 \leq k \leq N-1$, take the values from the $M$-QAM symbol set

$$\mathcal{X} = \{d(2l - \sqrt{M} - 1) + j \ d(2q - \sqrt{M} - 1), 1 \leq l, q \leq \sqrt{M}\},$$

where $2d$ is the minimum distance between symbol points. For notational simplification, we will drop the block index $[s]$ in the sequel. Adding the cyclic prefix (CP) of length $N_{cp}$ to $x$ yields

$$\hat{x} = [x_{-N_{cp}} \ x_{-N_{cp}+1} \ \cdots \ x_{-1} \ | \ x^T]^T,$$  

in which $x_{-k} = x_{N-k}$ for $1 \leq k \leq N_{cp}$. The signal block $\hat{x}$ is amplified by the HPA to yield the actually transmitted signal vector

$$\hat{w} = [w_{-N_{cp}} \ w_{-N_{cp}+1} \ \cdots \ w_{-1} \ | \ w^T]^T$$

where

$$w_k = \Psi(x_k), -N_{cp} \leq k \leq N - 1,$$

in which $\Psi(\cdot)$ represents the CV static nonlinearity of the transmitter HPA, and $w_{-k} = w_{N-k}$ for $1 \leq k \leq N_{cp}$. We consider the solid state power amplifier [6], [7], whose nonlinearity $\Psi(\cdot)$ is constituted by the HPA’s amplitude response $A(r)$ and phase response $\Upsilon(r)$ given by

$$A(r) = \frac{g_a}{1 + \left(\frac{g_a}{A_{sat}}\right)^{\frac{2\beta_a}{\alpha_a}}},$$

$$\Upsilon(r) = \frac{\alpha_0 r^{q_1}}{1 + \left(\frac{r}{r_T}\right)^{q_2}},$$

where $r$ denotes the amplitude of the input to the HPA. $g_a$ is the small gain signal, $\beta_a$ is the smoothness factor and $A_{sat}$ is the saturation level, while the parameters of the phase response, $\alpha_0, \beta_a, q_1$ and $q_2$, are adjusted to match the specific amplifier’s characteristics. The NEC GaAs power amplifier used in the standardization [6], [7] has the parameter set

$$g_a = 19, \ \beta_a = 0.81, \ A_{sat} = 1.4;$$

$$\alpha_0 = -48000, \ \beta_a = 0.123, \ q_1 = 3.8, \ q_2 = 3.7.$$  

Hence, given the input $x_k = |x_k| \cdot e^{j \phi x_k}$, the output of the HPA can be expressed as

$$w_k = A(|x_k|) \cdot e^{j \left(\phi x_k + \Upsilon(|x_k|)\right)}.$$  

The operating status of the HPA may be specified by the output back-off (OBO), which is defined as the ratio of the maximum output power $P_{\text{max}}$ of the HPA to the average output power $P_{\text{aop}}$ of the HPA output signal, given by

$$\text{OBO} = 10 \cdot \log_{10} \frac{P_{\text{max}}}{P_{\text{aop}}}.$$  

The smaller OBO is, the more the HPA is operating into the nonlinear saturation region.

The amplified signal $\hat{w}$ is transmitted through the channel whose CIR coefficient vector is expressed by

$$h = [h_0 \ h_1 \ \cdots \ h_{L_{\text{cir}}}]^T.$$  

The CIR length satisfies $L_{\text{cir}} \leq N_{cp}$. It is assumed that $h_0 = 1$ because if this is not the case, $h_0$ can always be absorbed
into the CV static nonlinearity $\Psi(\cdot)$, and the channel impulse response coefficients are re-scaled as $h_i/|h_0|$ for $0 \leq i < L_{\text{cir}}$. At the receiver, after the CP removal, the channel-impaired received signals $y_k$ are given by

$$y_k = \sum_{i=0}^{L_{\text{cir}}} h_i w_{k-i} + e_k, \quad 0 \leq k \leq N - 1,$$

(12)
in which $w_{k-i} = w_{N+k-i}$ for $k < i$, where $e_k = e_{k+i} \vdots e_{k_1}$ is the channel AWGN with $E\{e_{k+i}\} = E\{e_{k_1}\} = \sigma_e^2$. Because $N_{\text{ep}} \geq L_{\text{cir}}$, the CP removal at the receiver automatically cancels the inter block interference and transfers the linear convolution channel into the circular one. Passing $y = [y_0 \ y_1 \cdots y_{N-1}]^T$ through the $N$-point FFT processor yields the FD received signal vector

$$Y = [Y_0 \ Y_1 \cdots Y_{N-1}]^T = FY,$$

(13)
where

$$F = \frac{1}{\sqrt{N}} \begin{bmatrix} 1 & 1 & \cdots & 1 & e^{-j2\pi/N} & \cdots & e^{-j2\pi(N-1)/N} \\ 1 & e^{-j2\pi/N} & \cdots & e^{-j2\pi(N-1)/N} & \vdots & \vdots & \vdots \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 1 & e^{-j2\pi(N-1)/N} & \cdots & e^{-j2\pi(N-1)(N-1)/N} \end{bmatrix},$$

(14)
is the FFT matrix which has the orthogonal property of $F^H F = F^H F = I$. The elements of $Y$ are given by

$$Y_n = H_n W_n + \Xi_n, \quad 0 \leq n \leq N - 1,$$

(15)
where $\Xi_n = \Xi_{n+N} \vdots \Xi_{N}$ is the FD channel AWGN with $E\{\Xi_{n+N}^2\} = E\{\Xi_{n+1}^2\} = \sigma_e^2$, and the frequency domain channel transfer function coefficients (FDCTFCs) $H_n$ for $0 \leq n \leq N - 1$ are given by the $N$-point FFT of $h$

$$[H_0 \ H_1 \cdots H_{N-1}]^T = FH,$$

(16)
while

$$W = [W_0 \ W_1 \cdots W_{N-1}]^T = FW$$

(17)
is the $N$-point FFT of $w$. Note that $w$ is unobservable and, therefore, neither $w$ nor $W$ is available at the receiver. If we denote $\Xi = [\Xi_0 \ \Xi_1 \cdots \Xi_{N-1}]^T$, the FD received signal (15) can be expressed concisely as

$$Y = \text{diag}(H_0, H_1, \cdots, H_{N-1}) W + \Xi = \text{diag}(H_0, H_1, \cdots, H_{N-1}) FW + \Xi.$$  

(18)
Given the FDCTFCs $H_n$ for $0 \leq n \leq N - 1$, the FD one-tap zero-forcing equalisation is given by

$$\hat{W}_n = \frac{Y_n}{H_n}, \quad 0 \leq n \leq N - 1.$$  

(19)
Performing the $N$-point inverse FFT (IFFT) on $\hat{W}$ yields

$$\hat{w} = [\hat{w}_0 \ \hat{w}_1 \cdots \hat{w}_{N-1}]^T = F^H \hat{W} = \Phi(x) + F^H \hat{\Xi},$$  

(20)
where $\hat{\Xi} = \text{diag}(H_0^{-1}, H_1^{-1}, \cdots, H_{N-1}^{-1}) \Xi$, and

$$\Phi(x) = [\Phi(y_0) \ \Phi(x_1) \cdots \ \Phi(x_{N-1})]^T = [\hat{w}_0 \ \hat{w}_1 \cdots \hat{w}_{N-1}]^T.$$  

(21)
If the HPA $\Psi(\cdot)$ at the transmitter were linear, $\hat{w}_k$ would be an estimate of the transmitted data symbol $x_k$. But $\Psi(\cdot)$ is nonlinear, and the linear equalisation (19) alone is no longer sufficient for estimating $x$. If the nonlinearity $\Psi(\cdot)$ is known and it is invertible, then the effects of $\Psi(\cdot)$ can be compensated by inverting it. Specifically, an estimate of the transmitted data vector $x$ is given by

$$\hat{x} = \Psi^{-1}(\hat{w}) = [\Psi^{-1}(\hat{w}_0) \ \Psi^{-1}(\hat{w}_1) \cdots \ \Psi^{-1}(\hat{w}_{N-1})]^T.$$  

(22)

III. NONLINEAR SC-FDE OF HAMMERSTEIN SYSTEM

A. Identification of the Hammerstein channel

Given the input $x_k$ to the HPA, we model the HPA’s nonlinear amplitude response and phase response by the two RV univariate B-spline neural networks

$$\hat{A}(|x_k|) = \sum_{l=1}^{N_0} B_l^{(P_0)}(|x_k|) \omega_l,$$

(23)
and

$$\hat{T}(|x_k|) = \sum_{l=1}^{N_0} B_l^{(P_0)}(|x_k|) \theta_l,$$

(24)
where $N_0$ is the number of B-spline basis functions, $(P_0 - 1)$ is the order of the piecewise polynomial and the B-spline basis functions $B_l^{(P_0)}(r)$ are calculated based on the De Boor algorithm given in Appendix A, while $\omega = [\omega_1 \ \omega_2 \cdots \omega_{N_0}]^T$ and $\theta = [\theta_1 \ \theta_2 \cdots \theta_{N_0}]^T$ are the parameter vectors of the two RV B-spline models to be determined. The predicted HPA’s output can then be expressed as

$$\hat{y}_k = \hat{A}(|x_k|) \cdot e^{|z_k + \hat{T}(|x_k|)|}.$$  

(25)
The identification task is to jointly estimate the CIR vector $h$ and the parameter vectors $\{\omega, \theta\}$ based on a block of training data $\{x_k, y_k\}_{k=0}^{N-1}$ by minimising the cost function

$$J_1(h, \omega, \theta) = \frac{1}{N} \sum_{k=0}^{N-1} \hat{e}_k = \frac{1}{N} \sum_{k=0}^{N-1} |y_k - \hat{y}_k|^2$$

(26)
subject to the constraint $h_0 = 1$, in which $\hat{y}_k$ is given by

$$\hat{y}_k = \sum_{i=0}^{L_{\text{cir}}} h_i \hat{w}_{k-i} = \sum_{i=0}^{L_{\text{cir}}} h_i \hat{A}(|x_k|) \cdot e^{|z_{k-i} + \hat{T}(|x_{k-i}|)|},$$

(27)
where $x_{k-i} = x_{N+k-i}$ and $\hat{w}_{k-i} = \hat{w}_{N+k-i}$ if $k < i$. By denoting $\hat{e} = [\hat{e}_0 \ \hat{e}_1 \cdots \hat{e}_{N-1}]^T$ and $y = [y_0 \ y_1 \cdots y_{N-1}]^T$ over the training data set, the system can be expressed as

$$y = Ph + \hat{e},$$

(28)
where the regression matrix $P \in \mathbb{C}^{N \times (L_{\text{cir}}+1)}$ is given by

$$P = \begin{bmatrix} \hat{w}_0 & \hat{w}_{-1} & \cdots & \hat{w}_{-L_{\text{cir}}} \\ \vdots & \vdots & \ddots & \vdots \\ \hat{w}_k & \hat{w}_{k-1} & \cdots & \hat{w}_{k-L_{\text{cir}}} \\ \vdots & \vdots & \ddots & \vdots \\ \hat{w}_{N-1} & \hat{w}_{N-2} & \cdots & \hat{w}_{N-1-L_{\text{cir}}} \end{bmatrix}.$$  

(29)
Therefore, given $\omega$ and $\theta$, $\hat{w}_k$ for $-L_{\text{cir}} \leq k \leq N - 1$ are fixed, and we have the LS estimate of $h$ readily given by

$$\hat{h} = (P^H P)^{-1} P^H y. \quad (30)$$

When $h$ is fixed, the FDE (19) can be carried out and the corresponding TD signal $\hat{w}_k$ of (20) can be calculated based on which we estimate $\{\omega, \theta\}$ by solving the optimisation

$$\min_{\omega, \theta} J_2(\omega, \theta) = \min_{\omega, \theta} \frac{1}{N} \sum_{k=0}^{N-1} \left| \hat{w}_k - \hat{A}(x_k) e^{j\tau_k} \right|^2. \quad (31)$$

However, this is a complex nonlinear optimisation problem, requiring iterative calculation. To get around this difficulty, we relax our optimisation task into the two simultaneous objectives for $\omega$ and $\theta$, respectively,

$$\min_{\omega} J_3(\omega) = \min_{\omega} \frac{1}{N} \sum_{k=0}^{N-1} \left( |\hat{w}_k| - \sum_{i=1}^{N_k} B_i^*(p_i)(|x_k|) \omega \right)^2, \quad (32)$$

$$\min_{\theta} J_4(\theta) = \min_{\theta} \frac{1}{N} \sum_{k=0}^{N-1} \left( |\tau_k| - \sum_{i=1}^{N_k} B_i^*(p_i)(|x_k|) \theta \right)^2, \quad (33)$$

where $-\pi < \gamma_k < \pi$ is the principle value of $\arctan \hat{w}_k$. The LS estimates of $\omega$ and $\theta$ are given respectively by

$$\hat{\omega} = (B^T B)^{-1} B^T \hat{w}, \quad (34)$$

$$\hat{\theta} = (B^T B)^{-1} B^T \gamma, \quad (35)$$

where $[\hat{w}]^T = [[\hat{w}_0] [\hat{w}_1] \cdots [\hat{w}_{N-1}]]^T$, and the regression matrix $B \in \mathbb{R}^{K \times N_k}$ with

$$B = \left[ \begin{array}{cccc}
B_1^*(p_1)(x_0) & B_2^*(p_2)(x_0) & \cdots & B_{N_k}^*(p_{N_k})(x_0) \\
B_1^*(p_1)(x_1) & B_2^*(p_2)(x_1) & \cdots & B_{N_k}^*(p_{N_k})(x_1) \\
\vdots & \vdots & \ddots & \vdots \\
B_1^*(p_1)(x_{N-1}) & B_2^*(p_2)(x_{N-1}) & \cdots & B_{N_k}^*(p_{N_k})(x_{N-1})
\end{array} \right]. \quad (36)$$

Note that although $J_3(\omega)$ and $J_4(\theta)$ are not exactly equivalent to $J_2(\omega, \theta)$, they serves the same purpose of minimising the misalignment between the predicted HPA output $\hat{w}_k$ by the two B-spline models to the desired output $\tilde{w}_k$. Using $J_3(\omega)$ and $J_4(\theta)$ however can bring significant computational advantage, since we have the closed-form LS solutions of $\omega$ and $\theta$ given fixed $h$. We adopt the following ALS algorithm, which is a coordinate gradient descent algorithm [20], [21], to estimate $h$ as well as $\omega$ and $\theta$. The coordinate gradient descent approach transforms a difficult optimisation task into easier subtasks by fixing some variables in turn and solving the remaining variables. Unlike a generic coordinate gradient descent algorithm, in our case we have the closed-form solutions of $h$ as well as $\omega$ and $\theta$ for the both subtasks.

**Initialisation.** Initialise $\tilde{w}_k = x_k$ in $P$ of (29). Calculate $h$ as the LS estimate given by $\hat{h}^{(0)} = (P^H P)^{-1} P^H y$. Then obtain $\hat{h}^{(0)}$ by normalising $h_i \leftarrow h_i/h_0$ for $0 \leq i \leq L_{\text{cir}}$.

**ALS estimation.** For $1 \leq \tau \leq \tau_{\text{max}}$, where $\tau_{\text{max}}$ is the maximum number of iterations, perform:

a) Fix $h$ to $\hat{h}^{(\tau-1)}$, and obtain $\tilde{w}$ using (16), (19) and (20). Then calculated $\hat{\omega}^{(\tau)}$ and $\hat{\theta}^{(\tau)}$ using (34) and (35).

b) For $P$ of (29), compute $\tilde{w}_k$ according to (25) based on $\hat{\omega}^{(\tau)}$ and $\hat{\theta}^{(\tau)}$. Calculate $\hat{h}^{(\tau)}$ using (30). Then obtain $\hat{h}^{(\tau)}$ by normalising $h_i \leftarrow h_i/h_0$ for $0 \leq i \leq L_{\text{cir}}$.

A few iterations, i.e. a very small $\tau_{\text{max}}$ are sufficient for the above ALS estimation procedure to converge.

**B. Inversion of the HPA’s Nonlinear Amplitude Response**

Given the CV Hammerstein channel’s static nonlinearity $\Psi(\ )$, we wish to compute its inverse defined by $x_k = \Psi^{-1}(w_k)$. From (9), we have

$$|x_k| = A^{-1}(|w_k|), \quad (37)$$

$$\zeta_k^x = \zeta_k^w - \Theta(|x_k|). \quad (38)$$

Therefore, given the estimated HPA’s amplitude response $\hat{A}(\ )$ and phase response $\hat{\Theta}(\ )$ specified by (23) and (24), we only need to find the inversion of $\hat{A}(\ )$. We adopt the following B-spline neural network\(^1\) to model $\hat{A}^{-1}(\ )$.

$$|\hat{x}| = \hat{A}^{-1}(|w|) = \sum_{i=1}^{N_k} B_i^*(p_i)(|w|)\alpha_i. \quad (39)$$

In order to learn this inverse mapping or to estimate the parameter vector $\alpha = [\alpha_1 \alpha_2 \cdots \alpha_{N_k}]^T$, a training data set $\{\tilde{w}_k, |x_k|\}_{k=0}^{N-1}$ would be needed but $w_k$ is unobservable and, therefore, is not available. Fortunately, as a byproduct of the Hammerstein channel identification presented in Section III-A, we already obtain an estimate for $w_k$ as $\hat{w}_k$ which is given in (25). Therefore, the pseudo training data $\{\tilde{w}_k, |x_k|\}_{k=0}^{N-1}$ can be utilised to estimate the inverse mapping (39). More specifically, by defining

$$\hat{\alpha} = (\hat{B}^T \hat{B})^{-1} \hat{B}^T |x| \in \mathbb{R}^{K \times N_k}$$

$$\hat{B} = \left[ \begin{array}{cccc}
B_1^*(p_1)(|\tilde{w}_0|) & B_2^*(p_2)(|\tilde{w}_0|) & \cdots & B_{N_k}^*(p_{N_k})(|\tilde{w}_0|) \\
B_1^*(p_1)(|\tilde{w}_1|) & B_2^*(p_2)(|\tilde{w}_1|) & \cdots & B_{N_k}^*(p_{N_k})(|\tilde{w}_1|) \\
\vdots & \vdots & \ddots & \vdots \\
B_1^*(p_1)(|\tilde{w}_{N-1}|) & B_2^*(p_2)(|\tilde{w}_{N-1}|) & \cdots & B_{N_k}^*(p_{N_k})(|\tilde{w}_{N-1}|)
\end{array} \right]. \quad (40)$$

the LS solution of $\alpha$ is readily given by $\hat{\alpha} = (\hat{B}^T \hat{B})^{-1} \hat{B}^T |x|$ in which $|x| = [\tilde{x}_0 \tilde{x}_1 \cdots |x_{N-1}|]^T$.

During the data detection, given the estimated CIR vector $\hat{h}$, the estimated nonlinear phase response $\hat{\Theta}(\ )$ and the estimated inverse nonlinear amplitude response $\hat{A}^{-1}(\ )$, the linear equalised TD signal $\hat{w}$ can be computed according to (16), (19) and (20). The estimate of the transmitted data $x_k$ can then be given by $\hat{x}_k = \hat{e}^{\zeta_k^x}$ with $|\hat{x}_k| = \hat{A}^{-1}(|\tilde{w}_k|)$ and $\zeta_k^x = \zeta_k^w - \hat{\Theta}(|\tilde{x}_k|)$.\(^1\)
IV. Simulation Study

We considered a Hammerstein SC-FDE System in which the HPA employed was described by (6) and (7) with the parameter set given in (8). The size of the transmitted data block was set to \( N = 2048 \) and 64-QAM was used. We assumed a quasi-static Rayleigh multipath channel with an exponentially decreasing power delay profile, where the average gain for the \( l \)th path was given by

\[
E\{ |h_l| \} = \frac{\eta}{L_{\text{cir}}}, \quad 0 \leq l \leq L_{\text{cir}},
\]

with \( \eta \) being the channel degradation factor. In the simulation study, we set \( \eta = 3 \) and \( L_{\text{cir}} = 9 \). The CIR coefficients \( h_l \) for \( 0 \leq l \leq L_{\text{cir}} \) remained constant during the communication session. We used a full data block with \( N = 2048 \) training samples in the joint estimation of the CIR coefficient vector \( h \) and the parameter vectors \( \omega \) and \( \theta \) of the two B-spline models for \( \Psi(\cdot) \) as well as the estimation of the parameter vector \( \alpha \) of the inverting B-spline model for \( A^{-1}(\cdot) \). The piecewise quadratic polynomial of \( P_o = 2 \) was chosen as the B-spline basis function, and the number of B-spline basis functions in all three B-spline neural networks was set to six. The empirically determined knot sequences for \( |x| \) and \( |\hat{w}_b| \) are listed in Table I. The system’s signal-to-noise ratio (SNR) was defined as SNR = \( E_b/N_o \), where \( E_b \) was the average power of the input signal \( x_k \) to the HPA and \( N_o = 2\sigma^2 \) was the channel AWGN’s power.

The identification experiments were conducted under the HPA operation conditions of \( \text{OBO} = 5 \) dB and \( \text{OBO} = 2 \) dB, respectively, as well as two given SNR conditions of \( \text{SNR} = 0 \) dB and \( \text{SNR} = 10 \) dB, respectively. The identification results of the linear subsystem in the Hammerstein channel under the four experimental conditions are summarised in Table II, while the modelling results of the HPA static nonlinearity \( \Psi(\cdot) \) by the estimated \( \hat{\Psi}(\cdot) \) as represented by the two B-spline neural networks are illustrated in Fig. 1. It can be seen from Table II that the CIR estimates achieve high accuracy for all the four conditions. The results of Fig. 1 clearly demonstrate the capability of the proposed two RV B-spline neural networks to accurately model the HPA’s nonlinear amplitude and phase response, respectively.

The combined response of the HPA’s true nonlinearity and its estimated inversion obtained under the condition of \( \text{OBO} = 2 \) dB and \( \text{SNR} = 10 \) dB is depicted in Fig. 2. The result of Fig. 2 demonstrates the capability of the B-spline neural network to accurately model the inversion of the HPA’s nonlinearity based only on the pseudo training data. The effectiveness of the proposed nonlinear SC-FDE scheme is illustrated in Fig. 3, where the nonlinear SC-FDE was constructed based on the estimated CIR \( \hat{h} \), the estimated HPA’s phase response \( \hat{T}(\cdot) \) and the estimated inverse mapping for the HPA’s amplitude response \( \hat{A}^{-1}(\cdot) \), obtained under the two simulation conditions. The achievable BER performance of the proposed nonlinear SC-FDE are plotted in Fig. 4 under three different operating conditions of the HPA, in comparison to the BER performance obtained by the standard linear SC-FDE. Clearly, the standard SC-FDE is incapable of compensating the nonlinear distortions of the Hammerstein channel and its attainable BER performance is very poor even under the HPA operating condition of \( \text{OBO} = 5 \) dB, as can be seen from Fig. 4. By contrast, the proposed nonlinear SC-FDE constructed based on the estimated CIR and the inverse mapping of the HPA is able to compensate most of the nonlinear distortions and attains a much better BER performance.

V. Conclusions

A novel nonlinear SC-FDE scheme has been developed for the Hammerstein channel that includes the significant nonlin-
Fig. 1. Comparison of the HPA’s static nonlinearity $\Psi(\cdot)$ and the estimated static nonlinearity $\hat{\Psi}(\cdot)$ under: (a) $OBO = 5$ dB, $E_b/N_0 = 0$ dB; (b) $OBO = 5$ dB, $E_b/N_0 = 10$ dB; (c) $OBO = 2$ dB, $E_b/N_0 = 0$ dB; and (d) $OBO = 2$ dB, $E_b/N_0 = 10$ dB.
We have proposed to utilise two RV B-spline neural networks for modelling the HPA’s nonlinear amplitude and phase responses, respectively, and have derived an efficient ALS scheme to estimate the CIR coefficient vector as well as the parameter vectors of the two B-spline models that represent the HPA’s nonlinearity. Moreover, an additional RV B-spline neural network has been utilised to model the inverse mapping of the HPA’s amplitude response, and we have shown that the parameter vector of this inverting B-spline model can readily be obtained as the closed-form LS solution based on the pseudo training data obtained as a natural byproduct of the Hammerstein channel identification. Simulation results have demonstrated that our proposed identification procedure is capable of accurately estimating the Hammerstein channel as well as the inverse mapping of the channel’s static nonlinearity. The results obtained have also confirmed the effectiveness of the proposed nonlinear SC-FDE scheme constructed based on the estimated CIR and inverse B-spline mapping.
of predetermined knots (42), the set of basis functions can be formed by using the De Boor recursion [22], yielding for \( l \leq N + P_0 \),

\[
B_l^{(0)}(r) = \begin{cases} 
1, & \text{if } R_{l-1} \leq r \leq R_l, \\
0, & \text{otherwise},
\end{cases}
\]

(43)

as well as for \( l = 1, \ldots, N + P_0 - p \), and \( p = 1, \ldots, P_0 \),

\[
B_l^{(p)}(r) = \frac{r - U_{l-1}}{U_{p+t-1} - U_{l-1}} B_l^{(p-1)}(r) + \frac{U_{p+t} - r}{U_{p+t} - U_l} B_{l+1}^{(p-1)}(r).
\]

(44)

Note that, due to the piecewise nature of B-spline functions, there are only \( P_0 + 1 \) basis functions with nonzero functional values at any point \( r \). Hence, the complexity of the De Boor algorithm is determined by the polynomial order \( P_0 \), rather than the number of knots, and this is in the order of \( O(P_0^2) \).
