Abstract

Decomposition is a technique to separate the design of a complex system into smaller sub-models, which improves scalability and team development. In the shared-variable decomposition approach for Event-B, sub-models share external variables and communicate through external events which cannot be easily refined.

Our first contribution hence is a proposal for a new construct called interface that encapsulates the external variables, along with a mechanism for interface instantiation. Using the new construct and mechanism, external variables can be refined consistently. Our second contribution is an approach for verifying the correctness of Event-B extensions using the supporting Rodin tool. We illustrate our approach by proving the correctness of interface instantiation.

Keywords: Event-B, Decomposition, Refinement, External variables, Interface instantiation

1. Introduction

When decomposing a model into sub-models we intend to continue refining the sub-models independently of each other while preserving the properties of the full model. A suitable decomposition method for Event-B has been proposed by Abrial [1]. It partitions events of a model between its sub-models. Variables of the model are split correspondingly into external variables shared by the sub-models and internal variables private to each sub-model. For all external variables of a sub-model, external events that mimic the effect of corresponding (internal) events of other sub-models have to be added. If we want to refine external variables, we have to provide a gluing invariant that is functional, say, \( v = h(w) \) where \( v \) are the abstract variables and \( w \) the concrete variables. Abrial [1] also proposes to rewrite the external events with \( v := h(w) \) so that concrete and abstract events are equivalent. Internal variables and internal events are refined as usual in Event-B [2].

\ast Corresponding author
We propose a practical method for external event refinement that aids in structuring and understanding complex models. This requires a trade-off between generality and practicality. We believe that it would be difficult to generalise the method that we propose without sacrificing its practicality. The theory of the method is not difficult. Our aim is to make using a difficult technique, the refinement of external variables and external events in Event-B, as easy as possible.

We call a collection of external variables with the external invariants an interface. Modelling interfaces “manually” by marking the corresponding variables as being external and refining them by specifying functional invariants makes it difficult to decompose and refine a model repeatedly. Fig. 1 illustrates the problem where a model $M$ is decomposed three times and the resulting sub-models are refined. We are interested in the two sub-models $M_1$ and $M_2$ at the bottom. How do we find the shared external invariants?

The lists of variables $w_1$, $w_2$, $v_1$ and $v_2$ are not necessarily disjoint. Let $w$ be the list of variables occurring in $w_1$ or $w_2$ and $v$ be the list of variables occurring in $v_1$ or $v_2$. We need to find one suitable external invariant $v = h(w)$ to be used in the sub-models $M_1$ and $M_2$. What is the shape of $h$? Furthermore, when refining $M_2$ we have to think about the necessary changes to $M_1$. As a consequence of the current situation, interfaces are refined to implementation level before decomposition. This complicates the use of decomposition on higher levels of abstraction. We would prefer a method where the necessary reasoning can be restricted to one place. The functional invariant $h$ should be evident and easily maintainable also in the face of potential changes to the sub-models and the interfaces.

Using our approach of interface instantiation this can be done. Because we are treating instantiation as a special form of refinement, we can combine interface instantiation steps with refinement steps. This gives us some liberty in arranging complex refinements. We also encourage a decomposition style where a separate theory of interface instantiation is maintained. We think that this contributes substantially to obtain models that are easier to understand and to modify. Interface instantiation supports a more incremental approach to decomposition because modifications that concern several components can be confined to only one place: the interface.

We call the very specific form of interface refinement that we use interface
instantiation. To be useful, it should
(i) be more liberal than \[1\] while not increasing the proof effort,
(ii) help to structure complex mixtures of decomposition and refinement,
(iii) work seamlessly with Event-B as it is. (It should not depend on transla-
tions.)

We argue by means of a case study that we have achieved this. The case study
addresses a difficulty of relating Event-B refinement to Problem Frames elabo-
ration \[12\] discussed in \[7\]. It has been composed from \[7\] and \[15\]. We have
down-sized it in order to focus on the problem of the refinement of external
variables, that is, the interfaces. We have a tool for decomposition \[18\] but
we do not have implemented a software tool for interface instantiation. Instan-
tiation of carrier sets has been implemented similarly internally in the ProB
tool \[14\], in order to achieve better performance when model checking and con-
straint checking \[7\]. The case study as presented in \[15\] uses Problem Frames to
achieve traceability of requirements. We have not used Problem Frames in this
article because they are not required to explain interface instantiation. This
also permits us to cast the problem entirely in Event-B terminology. However,
the proposed method of instantiation could be used with Problem Frames as
employed in \[7, 15\]. This work extends prior work presented in \[9\] by allowing
instantiations in a lattice of interfaces.

In the modularisation approach for Event-B presented in \[11\], the notion of
interface has been used to capture software specifications using some interface
variables and operations acting on these variables. The intention behind the use
of interfaces is to separate specifications from their implementations. Our notion
of interface is intended to provide efficient support for refining external variables
following Abrial’s decomposition method for system models. There was an ear-
lier attempt at external variable refinement that is hinted at in the specification
of the proof obligation generator for the Rodin tool \[8\]. This was considered
too complicated and not feasible for large systems that are decomposed and
refined repeatedly. We think, that our approach solves the problem. Popple-
ton \[16\] discusses external refinement based on Abrial’s approach but also does
not provide a practicable technique for doing so. The approach of modelling
extensible records \[6\] also permits a form interface instantiation. A difficulty
with using this approach is caused by the explicit mathematical model used for
record representations and the need to specify always values for all fields of a
record. However, extensible records could be used with our approach where it
would appear useful. Behavioural interface refinement such as discussed in \[17\]
addresses changing traces sub-models can exhibit, usually adding new events.
It does not consider refinement of shared variables.

2. Event-B

Event-B models are described in terms of the two basic constructs: contexts
and machines. Contexts contain the static part of a model whereas machines
contain the dynamic part. Contexts may contain carrier sets, constants, ax-
ioms, and theorems, where carrier sets are similar to types \[2\]. A context \(D\)
may extend a collection of contexts $D_1, \ldots, D_n$. In this relationship we call $D$ the concrete context and $D_1, \ldots, D_n$ the abstract contexts. Machines provide behavioural properties of Event-B models. Machines may contain variables, invariants, theorems, and events. Variables $v$ describe the state of a machine. They are constrained by invariants $I(v)$. Theorems $L(v)$ describe consequences of the invariants, i.e., we have to prove $I(v) \Rightarrow L(v)$.

Events. Possible state changes (from $v$ to $v'$) are described by means of events. Each event is composed of a guard $G(t,v)$ and an action $x : S(t, x, v')$, where $t$ are parameters the event may contain and $x$ are some variables (a subset of $v$). We denote an event $e$ by

$$e \triangleq \text{any } t \text{ where } G(t,v) \text{ then } x : S(t, v, x') \text{ end } .$$

Nondeterministic action assigning $x$ to be an element of a set $E(t,v)$ is denoted by $x \in E(t,v)$. Deterministic actions are denoted by $x := E(t,v)$. We denote an event without parameters by

$$e \triangleq \text{when } G(v) \text{ then } x : S(v, x') \text{ end } ,$$

and an event without parameters and guard by

$$e \triangleq \text{begin } x : S(v, x') \text{ end } .$$

A special init event without parameters and guard is used for the initialisation.

**Example 1** (Model). We specify a system where a sender sends a set of messages to a receiver. In our model the sender keeps its messages in a variable $s$ and the receiver keeps the received messages in a variable $r$. To guarantee that only messages can be received that could have been sent, we require $r \subseteq s$. The messages are described abstractly in context $msg0$. The set of all messages in partitioned into proper messages $MSG$ and acknowledgements $ACK$:

```plaintext
context msg0
  constants MSG, ACK, S
  sets M
  axioms
  MSG \neq \emptyset \land ACK \neq \emptyset \land M = MSG \cup ACK \land MSG \cap ACK = \emptyset
  S \subseteq MSG
end ,
```

and the behaviour of the system is described by machine `sere0`,

```plaintext
machine sere0 sees msg0
  variables s, r
  invariants s \subseteq MSG \land r \subseteq s
  events
  event init \triangleq \text{begin } s, r := S, \emptyset \text{ end }
  event trans \triangleq \text{any } x \text{ where } x \in s \setminus r \text{ then } r := r \cup \{x\} \text{ end end } .
```
Message transfer is captured in one-shot with event \texttt{trans}. It is common in Event-B to start with a model as simple as this one and gradually add more detail to it by refinement \cite{2}.

\textit{Refinement.} A machine \( N \) can refine another machine \( M \). We call \( M \) the \textit{abstract} machine and \( N \) the \textit{concrete} machine. The state of the abstract machine is related to the state of the concrete machine by a \textit{gluing invariant} \( J(v, w) \) associated with the concrete machine \( N \), where \( v \) are the variables of the abstract machine and \( w \) the variables of the concrete machine. Each event \( e \) of the abstract machine is \textit{refined} by one or more concrete events \( f \).

\textbf{Example 2} (Refinement). We prepare the decomposition of the model into a sender and a receiver by refining machine \texttt{sere0} such that sender \texttt{snd} and receiver \texttt{rec} exchange messages by means of a channel \( m \). In the refined model the sender deletes messages from its buffer \( u \) after they have been sent. The sender and the receiver implement a simple hand-shaking protocol based on the two kinds of messages \texttt{MSG} and \texttt{ACK}. We extend \texttt{msg0} with two constants \( a \) and \( ma \),

context \texttt{msg1} extends \texttt{msg0}
\begin{verbatim}
  constants a, ma
  axioms
  ma ∈ MSG → ACK
  a ∈ ACK
end.
\end{verbatim}

Later, after decomposing the system into the sender and the receiver, these constants will allow us to refine behaviour that was underspecified in the abstraction. Effectively, we have moved the corresponding nondeterminism into a context. As a result, we can share their instantiation among the components and refine them consistently. (Incidentally, we already have followed this approach when introducing \texttt{S} in \texttt{msg0}.) The behaviour of the refined system is described by machine \texttt{sere1},

\begin{verbatim}
machine \texttt{sere1} refines \texttt{sere0} sees \texttt{msg1}
variables u, r, m
invariants u ⊆ s ∧ (\{m\} ∩ MSG) ⊆ s ∧ u ⊆ MSG ∧ r ⊆ MSG ∧ m ∈ M
events
  event init ≡ begin u, r, m := S, Ø, a end
  event snd ≡ any x where x ∈ u ∧ m ∈ ACK then m, u := x, u \{x\} end
  event rec refines trans ≡ when m ∉ r ∪ ACK
                       then r, m := r ∪ \{m\}, ma(m) end
end.
\end{verbatim}

We have introduced the redundant invariants \( u ⊆ MSG, r ⊆ MSG \) and \( m ∈ M \) to show where different invariants go when decomposing a machine. It may also be seen as a preparatory step for the decomposition permitting us to distribute some invariants of \texttt{sere1} across the components after decomposing the machine.
**Decomposition.** The idea of decomposition \([1, 4, 10]\) is to split a large model into smaller sub-models which can be handled more comfortably than the whole: one should be able to refine these sub-models independently. For the purpose of this article we limit the discussion to decomposition into two machines. Decomposition of a model \(M\) separates this model into sub-models \(M_1\) and \(M_5\). These sub-models can then be refined independently into machines \(N_1\) and \(N_5\). The correctness of the decomposition technique guarantees that the model \(N\), obtained by recomposing \(N_1\) and \(N_5\), is a refinement of the original model \(M\). Decomposition and recomposition are illustrated by Fig. 2. Note that recomposition is never explicitly carried out. It is only in principle possible. The central concern during modelling is to decompose an abstract machine and, subsequently, refine the different sub-models separately.

Let \(M\) be a machine with variables \(x_1, x_3, x_5\) and invariants \(I(x_1, x_3, x_5)\), \(I_1(x_1, x_3)\), \(I_3(x_3)\) and \(I_5(x_3, x_5)\). Furthermore, let \(e_1, e_2, e_4\) and \(e_5\) be events of \(M\), accessing different sets of variables as follows. Let

\[
\begin{align*}
e_1 &\triangleq \text{any } u_1 \text{ where } E_1(u_1, x_1) \text{ then } x_1 : \text{ }| \text{ } P_1(u_1, x_1, x'_1) \text{ end }, \\
e_2 &\triangleq \text{any } u_2 \text{ where } E_2(u_2, x_1, x_3) \text{ then } x_1, x_3 : \text{ }| \text{ } P_2(u_2, x_1, x_3, x'_1, x'_3) \text{ end }, \\
e_4 &\triangleq \text{any } u_4 \text{ where } E_4(u_4, x_3, x_5) \text{ then } x_3, x_5 : \text{ }| \text{ } P_4(u_4, x_3, x_5, x'_3, x'_5) \text{ end }, \\
e_5 &\triangleq \text{any } u_5 \text{ where } E_5(u_5, x_5) \text{ then } x_5 : \text{ }| \text{ } P(u_5, x_5, x'_5) \text{ end }.
\end{align*}
\]

Machine \(M\) can be decomposed into two separate machines: \(M_1\) with events \(e_1\) and \(e_2\); and \(M_5\) with events \(e_4\) and \(e_5\). This is illustrated in Fig. 3. As a result of the decomposition, \(M_1\) has private variables \(x_1\) and shared variables \(x_3\). Invariants \(I_1(x_1, x_3)\) and \(I_3(x_3)\) can be attached to \(M_1\). The resulting sub-machine \(M_1\)
has two internal events $e_1$ and $e_2$ and one external event $e_4^*$ which abstracts$^1$ $e_4$ projected on the state containing only $x_1$ and $x_3$, that is, $e_4^*$ abstracts the event any $u_4, x_5$ where $E_4(u_4, x_3, x_5)$ then $x_3 : \exists x_5\cdot P_4(u_4, x_3, x_5, x_3^\prime, x_5^\prime)$ end. Machine $M_5$ is similar to $M_1$, with the two internal events $e_4$ and $e_5$ and an external event $e_2^*$ that abstracts $e_2$ projected on $x_3$ and $x_5$. It has the private variables $x_5$ and the shared variables $x_3$. Machines $M_1$ and $M_5$ can be developed independently with the syntactical constraints that the shared variables cannot be removed and the external events can only be refined in a restricted way.

Note that invariant $I(x_1, x_3, x_5)$ is not copied to either $M_1$ or $M_5$. A possibility to use this invariant in one of the sub-models is to project also this invariant on the corresponding state using existential quantifier. Thus, $\exists x_5\cdot I(x_1, x_3, x_5)$ could be added as an invariant to $M_1$.

**Example 3** (Decomposition). We decompose the machine $\text{sender1a}$ into two machines $\text{sender1a}$ and $\text{receiver1a}$. The sender has an internal event $\text{snd}$ and an external event $\text{rec}$. We mark external events with an asterisk “$\ast$”.

machine $\text{sender1a}$ sees $\text{msg1}$
variables $u, m$
invariants $u \subseteq MSG \land m \in M$
events
  event init $\triangleq$ begin $u, m := S, a$ end
  event $\text{snd}$ $\triangleq$ any $x$ where $x \in u \land m \in \text{ACK}$ then $m, u := x, u \setminus \{x\}$ end
  event $\text{rec}\ast$ $\triangleq$ when $m \notin \text{ACK}$ then $m := ma(m)$ end
end .

The event $\text{snd}$ is a textual copy of the corresponding event from $\text{sender1}$, whereas $\text{rec}\ast$ is an abstraction of the corresponding event $\text{rec}$ from $\text{sender1}$. (Variable $r$ has been abstracted away. See the aside at the end of this example.) Thanks to the function $ma$ event $\text{rec}\ast$ is deterministic and assigns an identical value to $m$ as does the internal event $\text{rec}$ of the receiver below.

machine $\text{receiver1a}$ sees $\text{msg1}$
variables $r \ m$
invariants $r \subseteq MSG \land m \in M$
events
  event init $\triangleq$ begin $r, m := \emptyset, a$ end
  event $\text{snd}\ast$ $\triangleq$ when $m \in \text{ACK}$ then $m := MSG$ end
  event $\text{rec}\ast$ $\triangleq$ when $m \notin r \cup \text{ACK}$ then $r, m := r \cup \{m\}, ma(a)$ end
end .

Note that the assignment to $m$ in the external event $\text{snd}\ast$ has become non-deterministic as a consequence of the abstraction from $u$.

Aside. In principle, decomposition can be done by a decomposition tool such as [18]. The external event $\text{rec}\ast$ as produced by the decomposition tool would

$^1"e\ast\text{abstracts } e"$ is the same as “$e$ refines $e\ast$".
have the following shape:

\[
\text{rec } r \triangleq \text{any } r \text{ where } r \subseteq M \land m \notin r \cup \text{ACK} \text{ then } m := m a(m) \text{ end }.
\]

The tool automatically quantifies over the variables that are internal to another machine, in this case \( r \). Manual decomposition usually leads to clearer models, however, at the cost of having to “invent” suitable abstractions.

### 3. Instantiation

**Carrier set and constant instantiation.** Contexts can be extended as usual in Event-B but we allow additionally to specify expressions to instantiate constants and carriers sets. Abstract carriers sets \( s \) must be instantiated by type expressions \( e(t) \) and constants \( c \) can be instantiated by expressions \( f(t, d) \), i.e.,

\[
\text{context } C \quad \text{context } D \text{ extends } C \text{ with } s = e(t), c = f(t, d)
\]

The equalities specifying the instantiation are treated similarly to axioms. The abstract constants and carriers sets that are instantiated remain visible. By contrast, the instantiation proposed in [2] replaces constants and carrier sets in the instantiating context. Still, they are similar to [2]: The equations of the extends-clause are used to rewrite the abstract axioms. If this changes an axiom, that axiom must be proved to hold in the instantiating context. Otherwise, nothing needs to be proved. This ensures that instantiation itself does not introduce new facts. The instantiation proof obligation is

\[
B(t, d) \Rightarrow A(e(t), f(t, d)).
\]

In summary, conventional Event-B context extension is instantiation with identity. Only abstract axioms of \( C \) with instantiated constants need to be proved as theorems in \( D \). The other axioms are preserved by extension.

**Connecting machines to interfaces.** Interfaces are declared in contexts and used in machines by connecting a machine to the interface. The machines must see the corresponding context:

\[
\text{context } C \quad \text{machine } M
\]
\[
\text{interface } U \quad \text{sees } C
\]
\[
\text{fields } m \quad \text{connects } U
\]
\[
\text{constraints } P(m) \quad : \quad \text{end}
\]

The constraints of an interface can refer to all constants and carrier sets of the surrounding context. In machine \( M \) the fields \( m \) are treated like variables and the constraints \( P(m) \) like external invariants.
Example 4 (Interface). The two machines \texttt{sender1a} and \texttt{receiver1a} share the external variable \texttt{m}. This variable plus the constraint \( m \in M \) constitutes the interface between the machines. We state this formally in a context \texttt{msg2} that extends the context \texttt{msg1},

\[
\text{context msg2 extends msg1} \\
\text{interface itf2} \\
\text{fields m} \\
\text{constraints } m \in M \\
\text{end .}
\]

Instead of sharing the variable \texttt{m}, the two machines are connected by interface \texttt{itf2} replacing the variable \texttt{m} and invariant \( m \in M \) in each machine,

\[
\begin{align*}
\text{machine sender1b sees msg2} & \quad \text{machine receiver1b sees msg2} \\
\text{connects itf2} & \quad \text{connects itf2} \\
\text{variables } u & \quad \text{variables } r \\
\text{invariants } u \subseteq MSG & \quad \text{invariants } r \subseteq MSG \\
\vdots & \quad \vdots \\
\text{end} & \quad \text{end .}
\end{align*}
\]

Modifications to the interface of the two machines can now be carried out in one place, namely, the interface \texttt{itf2}.

Interface instantiation. Interfaces can be instantiated by specifying equalities \( m = h(n) \) for replacing fields of an abstract interface \texttt{m} by fields of a concrete interface \texttt{n}. The names on the right-hand side of the equation must not occur in the abstract interface. Let interface \texttt{V} be given by

\[
\text{context D extends C} \\
\text{interface V instantiates U with } m = h(n) \\
\text{fields } n \\
\text{constraints } Q(n) \\
\text{end .}
\]

The expression \( h \) is often composed of pair-expressions " \( \cdot \rightarrow \cdot \) " . Interface instantiations must be bijective: we have to prove that \( h^{-1} \) is a function. The constraints \( P(m) \) of \texttt{U} are contained in interface \texttt{V} as specified by the instantiation \( m = h(n) \), that is, they become \( P(h(n)) \). Similarly to machine variables, field names of interfaces cannot be reintroduced. Similarly to machine invariants, constraints are accumulated in by instantiation: the constraints of interface \texttt{V} are \( Q(n) \land P(h(n)) \). Fig. 4 illustrates the interaction between decomposition, interface instantiation and refinement.

Example 5 (Instantiation). The implementation of the sender-receiver system distinguishes proper messages from acknowledgements by a Boolean value. Messages are thus composed of an ID, the Boolean value indicating whether the message is proper or an acknowledgement, and the message contents. Formally,
the set of messages $M$ is instantiated by $ID \times B \times C$ and the other constants accordingly,

context msg3 extends msg2 with
- $M = ID \times B \times C$
- $MSG = ID \times \{F\} \times C$
- $ACK = ID \times \{T\} \times C$
- $a = b \mapsto T \mapsto h$
- $ma = (\lambda j, f, d \cdot j \in ID \land f = F \land d \in C \mid j \mapsto T \mapsto d)$

sets $ID, C$
- constants $b, h$
- axioms $b \in ID \land h \in C$
- interface itf3 instantiates itf2 with $m = i \mapsto t \mapsto c$
  - fields $i, t, c$
  - constraints $i \in ID \land t \in B \land c \in C$
end .

Note that the constant $S$ is not instantiated. It is not required that all carrier sets and constants be instantiated. The need for instantiation is usually determined by the refinement proofs in the connected machines. We have to prove that the instantiation of the carrier sets and constants $M, MSG, ACK, a$ and $ma$ is consistent, that is

$(ID \times \{F\} \times C) \cup (ID \times \{T\} \times C) = ID \times B \times C$ ,
$(ID \times \{F\} \times C) \cap (ID \times \{T\} \times C) = \varnothing$ ,
$(\lambda j, f, d \cdot j \in ID \land f = F \land d \in C \mid j \mapsto T \mapsto d) \in (ID \times \{F\} \times C) \rightarrow (ID \times \{T\} \times C)$ ,
$b \mapsto T \mapsto h \in ID \times \{T\} \times C$ .

Constraints of interfaces are only accumulated, hence, nothing needs to be proved about the instantiated interface.

**Interface instantiation lattice.** An interface $V$ may also instantiate several interfaces $U_1, \ldots, U_k$. This is only possible under the following condition that must be satisfied in $V$ for all fields $m$ of $V$ or some abstract interface: The fields instantiated in distinct interfaces $U_\ell$ and $U_r$ are distinct or have been instantiated
in a common abstract interface. (A similar restriction is used in Event-B for context extension to ensure that carrier sets and constants have unique declarations.) As a consequence of the instantiation condition we only need to verify the following for all fields \( m \) instantiated in \( V \) with \( m = h_0(n) \) and in \( U \) with \( m = h_\ell(n) \): 
\[
    h_0(n) = h_\ell(n).
\]

A development using interfaces may have different branches of sub-models with distinct interfaces that are joined ultimately so that all machines of a model agree on their interfaces. We illustrate this by way of the small example shown in Fig. 5. In the figure, an abstract interface \( T \) containing two abstract fields \( m_1 \) and \( m_2 \) is used by \( M_1 \) and \( M_2 \). The development of sub-models \( M_1 \) and \( M_2 \) instantiates the fields of the interfaces in different order. Interface \( T \) is instantiated by \( U_1 \) where \( m_1 \) is replaced by \( n_1 \) and \( m_2 \) is retained while \( M_1 \) is refined into \( N_1 \) using \( U_1 \). Similarly, \( M_2 \) is refined by \( N_2 \) using \( U_2 \) that replaces \( m_2 \) by \( n_2 \) and retains \( m_1 \). Finally, \( V \) instantiates the two interfaces \( U_1 \) and \( U_2 \). The new interface \( V \) is used to refine \( N_1 \) and \( N_2 \) into \( O_1 \) and \( O_2 \).

Such a lattice of interfaces allows us to vary the order in which different fields are instantiated in different branches of a development. In the course of this, we temporarily abandon the compositionality of the intermediate machines (here \( N_1 \) and \( N_2 \)), only to reestablish it later for the final machines \( O_1 \) and \( O_2 \), by connecting them to the same interface \( V \).

**External event refinement.** Using interface instantiation we permit refinement of external events. Consider the following external event \( e \) operating on the external variables \( x \) and its refinement \( f \) operating on the external variables \( y \).

The refinement of external variables is captured by the relationship of the form 
\[
    x = h(y).
\]
Note that external events do not refer to any internal variables: they can only refer to external variables of the corresponding model. Let

\[
    e \triangleq \text{any } u \text{ when } E(u, x) \text{ then } x :| P(u, x, x') \text{ end },
\]
\[
    f \triangleq \text{any } v \text{ when } F(v, y) \text{ with } W(u, v, x, y, y') \land x' = h(y') \text{ then } y :| Q(v, y, y') \text{ end },
\]

where \( W(u, v, x, y, y') \land x' = h(y') \) is the witness for the refinement of \( e \) by \( f \).

The witness incorporates the refinement of external variables with function \( h \).

Beside the proof obligations to prove that \( f \) is a refinement of \( e \), we also need to prove that \( f \) is refined by \( e \). The latter is proved using the same given witnesses by the following proof obligations. We abbreviate the hypothesis common to
proof obligations by
\[
L(x, y, u, x, x') = I(x) \land J(x, y) \land x = h(y) \land E(u, x) \land P(u, x, x')
\]
We have to prove witness feasibility,
\[
L(x, y, u, x, x') \Rightarrow (\exists v, y'. W(u, v, x, y') \land x' = h(y'))
\]
Because \(h\) is bijective, the existence of \(y'\) is trivial, and the proof obligation can be simplified to \(L(x, y, u, x, x') \land x' = h(y') \Rightarrow (\exists v, W(u, v, x, y', y'))\). We have to show that concrete external events display the same behaviour as abstract events, that is, that nondeterminism is not reduced. We prove guard weakening,
\[
L(x, y, u, x, x') \land W(u, v, x, y, y') \land x' = h(y') \Rightarrow F(v, y)
\]
and (co-)simulation,
\[
L(x, y, u, x, x') \land W(u, v, x, y, y') \land x' = h(y') \Rightarrow Q(v, y, y')
\]
Note that invariant preservation for the refinement of \(f\) by \(e\) can be derived from the invariant preservation for the refinement of \(e\) by \(f\) and the fact that we use the same witnesses.

Example 6 (Instantiation and refinement). The instantiated interface \(itf3\) is incorporated into the model by refining the machines \(sender1b\) and \(receiver1b\) connecting the refinements to the instantiated interfaces. In the refinement proof all equalities specified in \(msg3\) and \(itf3\) can be used. The sender is refined by the machine

\[
\text{machine sender2b refines sender1b sees msg3}
\]
\[
\text{connects itf3}
\]
\[
\text{variables } u
\]
\[
\text{events}
\]
\[
\text{event init } \triq u, i, t, c := S, b, T, h \text{ end}
\]
\[
\text{event snd } \triq \text{any } j, f, d \text{ where } j \mapsto f \mapsto d \in u \land t = T
\]
\[
\text{then } i, t, c, u := j, f, d, u \setminus \{j \mapsto f \mapsto d\} \text{ end}
\]
\[
\text{event rec* } \triq \text{when } t = F \text{ then } t := T \text{ end}
\]
end ,

and the receiver by the machine

\[
\text{machine receiver2b refines receiver1b sees msg3}
\]
\[
\text{connects itf3}
\]
\[
\text{variables } r
\]
\[
\text{events}
\]
\[
\text{event init } \triq r, i, t, c := \emptyset, b, T, h \text{ end}
\]
\[
\text{event snd* } \triq \text{when } t = T \text{ then } i \mapsto t \mapsto c :\in MSG \text{ end}
\]
\[
\text{event rec } \triq \text{when } i \mapsto t \mapsto c :\notin \text{ then } r, t := r \cup \{i \mapsto t \mapsto c\}, T \text{ end}
\]
end .
We must prove the simulation relationships between the events of sender2b and receiver2b and those of sender1b and receiver1b. Concerning the interface itf3, we have to show that its constraints are preserved by all events. Because the constraints of itf3 are equivalent to true, the proof is trivial.

Example 7 (Emulation of instantiation using bijections). Two tools are available for decomposition [18] and instantiation [5]. However, they transform Event-B machines syntactically producing component machines and instantiated machines that do not have a relationship to their abstractions or among each other. This approach makes it difficult to maintain complex models. Our approach improves the situation by offering interfaces and instantiation supported by the modelling formalism. Not having dedicated tool support for the instantiation method yet, we emulate the method by specifying bijections that model the equations between instantiated terms,

context msg2x extends msg1
sets ID, C
constants U, na, b, h, t
axioms
\[ t \in \text{ID} \times \text{B} \times \text{C} \Rightarrow \text{M} \]
\[ t^{-1}[\text{MSG}] = \text{ID} \times \{\text{F}\} \times \text{C} \]
\[ t^{-1}[\text{ACK}] = \text{ID} \times \{\text{T}\} \times \text{C} \]
\[ U = t^{-1}[S] \]
\[ na = (\lambda j, f, d \cdot j \in \text{ID} \wedge f = \text{F} \wedge d \in \text{C} \mid j \mapsto \text{T} \mapsto d) \]
\[ ma = t^{-1}\circ na\circ t \]
\[ b \mapsto \text{T} \mapsto h = t^{-1}(a) \]
end.

The most elaborate proof of this development using the emulation occurs when instantiating function ma. With instantiation support in place this would have been trivial using the fact that \( ma = \cdots \) as specified in context msg3. The difficulty in the proof of refinement emulating instantiation is caused by the need to use the bijection \( t \) so that the equation for the instantiation becomes \( ma = t^{-1}\circ na\circ t \). Similar complications occur for all other abstract constants \( x \) (and sets \( X \)) where the equations have the form \( x = t(y) \) (and \( X = t[Y] \)). In the refined machines the instantiation equations need to be stated in the invariants for the sender

machine sender2a refines sender1a sees msg2x
variables v, i, t, c
invariants u = \( t[v] \wedge m = t(i \mapsto t \mapsto c) \)
events
  event init ≜ begin v, i, t, c := U, b, T, h end
  event snd ≜ any j, f, d where j \mapsto f \mapsto d \in v \wedge t = T
  \quad \text{then } i, t, c, v := j, f, d, v \setminus \{j \mapsto f \mapsto d\} end
  event rec* ≜ when t = \text{F} then t := \text{T} end
end

13
and the receiver

    machine receiver2a refines receiver1a sees msg2x
      variables q, i, t, c
      invariants r = l[q] \land m = l(i \rightarrow t \rightarrow c)
      events
        event init \equiv begin q, i, t, c := \emptyset, b, T, h end
        event snd* \equiv when t = T then i \rightarrow t \rightarrow c :\in MSG end
        event rec \equiv when i \rightarrow t \rightarrow c \notin q \land t = F
          then q, t := q \cup \{i \rightarrow t \rightarrow c\}, T end
      end .

Finally, we want to point out that in context msg2x consistency between the different axioms is not assured. It is easily possible to specify a collection of inconsistent axioms and techniques are required to validate them as can be done, for instance, with the ProB tool [14].

4. Case study: modelling of a cruise control system

We present interface instantiation by means of a model of a cruise control system. The cruise control system permits the driver of a car to select a target speed that the vehicle should attain. The system will try to maintain the vehicle speed as close as possible to the target speed. Since our main interest is to discuss interface instantiation, we will only discuss the functionality of the cruise control system as far as necessary for that discussion. We have modelled the system using the Rodin tool [3], emulating instantiation similarly to the approach of [7]: interfaces are represented syntactically by a lexical convention and carrier set instantiation is modelled by suitable bijections. The purpose of this model is to check the consistency of our cruise control model by way of a similar model verified using the Rodin tool. It is difficult to draw conclusions about the power or ease of the proof method based on that formal model. The reason for this is a mismatch of the proof obligations between our approach and what can be done with the tool currently. For this case study this is acceptable because as with many industrial applications of formal methods the challenge of the original problem is in the size of the model and not in the difficulty of the specified formal properties.

4.1. Development strategy

We want to implement a cruise control system sy0 by three sub-models: the controller cr5, the engine en5 and the exterior ae1. Fig. 6 shows the sub-models and their interfaces. The implementations of the controller and the engine are connected by means of two interfaces: concrete speed and acceleration, psa, and concrete pedal signals translated and passed on from the exterior, psi. The interface to the exterior, aes, is kept abstract in the implementation. More abstract system models should not be forced to use the interfaces psa and psi but permit abstractions thereof as shown in Fig. 7. The details of the interfaces
should be introduced step by step, introducing the abstract interfaces \texttt{asa} and \texttt{asi} first. We prefer to refine the controller and the engine but keep the exterior abstract at first. We do not want to decide on all interfaces before decomposing system \texttt{sy0}: we have not decided yet on the shape of the implementation of sub-model \texttt{ae1} and of interface \texttt{aes}. Interface \texttt{aes} could be used to implement an interface to the exterior or it could be used for animation and visualisation [13], for instance. The problem we face is to fit the abstract sub-models of Fig. 7 between \texttt{sy0} and the implementation in Fig. 6.

4.2. The full model: refinement, decomposition and instantiation

We present an overview of the full model and discuss specific issues in subsequent sections. Fig. 8 shows the details of the development outlined in Fig. 6 with the abstract decomposed model of Fig. 7 incorporated at the top of the figure. The contexts \texttt{ctx0}, \texttt{ctx1}, \texttt{ctx2} and \texttt{ctx3} specify the interface instantiations as indicated on the right-hand side of the figure and accompanying instantiations of carrier sets and constants. Context extension is shown on the left-hand side of the figure. Machines that see a context are depicted in the box of the corresponding context. For instance, the abstract model \texttt{sy0} of the cruise control is shown in the box of context \texttt{ctx0}. Most of the development effort focuses in the two columns \texttt{en1} to \texttt{en5} (on the engine) and \texttt{cr1} to \texttt{cr5} (on the controller).

We do not discuss all aspects of the development but focus on the following four aspects of the engine and the controller development.

i. Interface introduction (Section 4.3): In order to decompose a machine some variables private to that machine become shared among the sub-machines. For these variables interfaces are specified and the sub-machines are connected to them.

ii. Mixing instantiation and refinement (Section 4.4): Usually, a change of the representation of shared variables needs to be accompanied by refinements of private variables. Furthermore, carrier set and constant instantiation can be used to support refinement of private variables.
iii. Repeated instantiation (Section 4.5): Details about interfaces are introduced incrementally. Hence, it is important that the process of instantiation can be repeated without difficulty.

iv. Instantiation branching (Section 4.6): If two branches in a development instantiate interface fields in different order, then there must be a common instantiation that permits recomposition of the sub-models.

4.3. Interface introduction

The abstract model. The model sy0 from which we start the development declares variables sig, cs, vs, md, ts, va modelling external signals sig, internal control signals cs, vehicle speed vs, control mode md, target speed ts and acceleration va. It does not connect to any interfaces. This means we can refine this model in the usual way. Context ctx0 declares constants ES, CS, VS, VA, VRA, etc., modelling external signals ES, control signals CS, vehicle speed VS, vehicle acceleration VA, restricted vehicle acceleration VRA. It postulates the axiom

\[ \text{VRA} \subseteq \text{VA} \] (1)

We have invented constant VRA to make the invariant more interesting. The constants determine the possible values of the variables by means of the invariant
The constant $C$ models “cruise control active”; $AC$ models “manual change of vehicle speed”; $NC$ models “cruise control not active”. Constants $CS$ and $VS$ are declared to be contained in carrier sets, for example, carrier set $K$ contains $CS$ and carrier set $S$ contains $VS$. The carrier sets themselves are not used in the machine. The reason for this is that they can only be instantiated by type expressions. However, the more common case is that we need to instantiate by some more constrained set. See, for example, the instantiations of $C$, $AC$ and $NC$ in Section 4.4.

**Events of the abstract model.** We discuss three events of machine $sy0$: event $\text{chm}$ (“change mode”) models an internal state change of the controller,

\[
\text{event chm} \triangleq \begin{align*}
\text{begin} & \quad \text{md} : | \text{md} \in \{C, AC, NC\} \land (\text{md} = C \implies \text{va} \in \text{VRA}) \quad \text{end} ;
\end{align*}
\]

event $\text{chaac}$ (“change acceleration in mode $AC$”) models output to the engine,

\[
\text{event chaac} \triangleq \begin{align*}
\text{when} & \quad \text{md} = AC \quad \text{then} \quad \text{va} : \in \text{VA} \quad \text{end} ;
\end{align*}
\]

event $\text{chcs}$ (“change control signals”) models input from the engine,

\[
\text{event chcs} \triangleq \begin{align*}
\text{begin} & \quad \text{cs} := \text{fcs}(\text{sig}) \quad \text{end} .
\end{align*}
\]

It would be tempting to specify in the abstract event $\text{chcs}$ the assignment $\text{cs} := \text{sig}$. However, this asserts that $\text{cs}$ and $\text{sig}$ have the same type. Once the system is decomposed, we would have to refine them in the same way. To avoid this, we have introduced function $\text{fcs}$ mapping from the type of $\text{sig}$ to the type of $\text{cs}$. Models always need to be prepared for decomposition. Our method of instantiation does not change this.

**Decomposition of the abstract model.** Decomposing $sy0$ into $ev0$ and $cr0$ we have to introduce interfaces $asa$ and $asi$: 

interface $asi$
fields $cs$
constraints $cs \in CS$

interface $asa$
fields $vs, va$
constraints $vs \in VS \land va \in VA$.

Machine $ev0$ has one internal variable $\text{sig}$ and connects to the two interfaces $asa$ and $asi$. Machine $cr0$ connects to the same interfaces and has two internal variables $ts$ and $md$. We split the events in the usual way depending on which variables and fields the events refer to. Except for the use of interfaces the decomposition method of [1] works as before.
### Table 1: Modes and submodes of the cruise control system

<table>
<thead>
<tr>
<th>Mode</th>
<th>Submode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NC</td>
<td>OFF</td>
<td>Ignition is on, cruise control initialised and switched off</td>
</tr>
<tr>

<td>REC</td>
<td>A reversible error has occurred</td>
</tr>
<tr>
<td>C</td>
<td>CRS</td>
<td>Cruise control is maintaining the target speed</td>
</tr>
<tr>
<td></td>
<td>RES</td>
<td>Target speed is approached from above or from below</td>
</tr>
<tr>
<td>AC</td>
<td>ACC</td>
<td>Cruise control is accelerating the car</td>
</tr>
<tr>
<td></td>
<td>DEC</td>
<td>Cruise control is decelerating the car</td>
</tr>
</tbody>
</table>

4.4. Mixing instantiation and refinement

**Instantiation.** We refine cr0 to cr1 by instantiating interface asa by csa while refining variable md by variable nd. The constraints and instantiation equalities of csa become part of the gluing invariant of cr1. The abstract constants VS, VA and VRA are instantiated by integer ranges: VS = mS .. MS, VA = mA .. MA and VRA = mRA .. MRA constrained by axioms

\[
\ldots \wedge 0 \in mRA \ldots MRA \wedge mA \leq mRA \wedge mRA \leq MRA \wedge MRA \leq MA \wedge \ldots \quad (2)
\]

To satisfy the instantiation proof obligation we have to verify that (2) implies (1).

For clarity we introduce a new name for the interface containing the instantiated constants: `interface csa instantiates asa`. Machine cr1 and ev1 now both need to be connected to interface csa replacing asa. The machine also need to see the extended context ctx1.

**Refinement.** Variable md is refined by instantiating the constants C, AC and NC, using the gluing invariant nd \( \in \) md, and constant instantiations \( C = \{CRS, RES\}, AC = \{ACC, DEC\}, NC = \{OFF, ERR, REC\} \). Table 1 gives an overview of the operation modes and submodes of the model of the cruise control system. Note, how closely constant instantiation and refinement are linked in the refinement of md. The type of the abstract variable md has been instantiated such that the gluing invariant simply becomes nd \( \in \) md.

4.5. Repeated instantiation

**First instantiation.** Continuing the development from cr1 and ev1, we first instantiate interface asi by csi

\[
\text{interface csi instantiates asi with } cs = (ps \mapsto cis \mapsto is) \\
\text{fields ps, cis, is} \\
\text{constraints } ps \in PS \wedge cis \in CIS \wedge is \in IS
\]

\(^2\text{Table adapted from [7].}\)
<table>
<thead>
<tr>
<th>Pedal Signal</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pbp</td>
<td>The brake pedal has been hit</td>
</tr>
<tr>
<td>pbe</td>
<td>An error has occurred in the brake subsystem</td>
</tr>
<tr>
<td>pcp</td>
<td>The clutch pedal has been hit</td>
</tr>
<tr>
<td>pce</td>
<td>An error has occurred in the clutch subsystem</td>
</tr>
<tr>
<td>pae</td>
<td>An error has occurred in the accelerator subsystem</td>
</tr>
</tbody>
</table>

Table 2: Concrete pedal signals of the cruise control system.

where $PS$, for “pedal signals”, is a constant of context ctx2. The context also declares two constants $PSE$ and $PSS$, for “pedal signals error” and “pedal signals success”, such that $PSE \subseteq PS \land PSS \subseteq PS \land PSE \cap PSS = \emptyset$. This is used for a first refinement of event chm into two events chme and chmn:

```
event chme refines chm \equiv 
  when ps \in PSS \cup PSE then nd :\in \{ERR, REC\} end 

event chmn refines chm \equiv 
  when ps \notin PSS \cup PSE 
  then nd :\mid nd' \in \{CRS, RES\} \Rightarrow va \in mRA \ldots MRA end .
```

Second instantiation. Subsequently we instantiate the interface csi by psi

```
interface psi instantiates csi with ps = (pbp \mapsto pbe \mapsto pcp \mapsto pce \mapsto pae) 
fields pbp, pbe, pcp, pce, pae, cis, is 
constraints pbp \in \mathbb{B} \land pbe \in \mathbb{B} \land pcp \in \mathbb{B} \land pce \in \mathbb{B} \land pae \in \mathbb{B}
```

representing the abstract pedal signals $ps$ by a bit vector of concrete pedal signals $pbp \mapsto pbe \mapsto pcp \mapsto pce \mapsto pae$. Table 2 gives an overview of the different concrete pedal signals. We instantiate the constants $PSE$ and $PSS$

- $PSE = \{bp \mapsto be \mapsto cp \mapsto ce \mapsto ae | T \in \{be, ce, ae\}\}$,
- $PSS = \{bp \mapsto be \mapsto cp \mapsto ce \mapsto ae | T \notin \{be, ce, ae\} \land T \in \{bp, cp\}\}$.

by and prove $PSE \cap PSS = \emptyset$ as postulated above.

Event chme is split (that is, refined into several events) according to different signal combinations.

```
event chmrb refines chme \equiv 
  when T \notin \{pbe, pce, pae\} \land T = pbp then nd := REC end 

event chmrc refines chme \equiv 
  when T \notin \{pbe, pce, pae\} \land T = pcp then nd := REC end 

event chmbe refines chme \equiv 
  when T = pbe then nd := ERR end 

event chmce refines chme \equiv 
  when T = pce then nd := ERR end 

event chmae refines chme \equiv 
  when T = pae then nd := ERR end .
```

This last instantiation is much more concise than the refinement suggested in [7]. We can avoid a lot of the overhead that is usually incurred by using refinement emulating instantiation.
4.6. Instantiation branching

In machine en3 event chvs is refined by replacing the abstract nondeterministic assignment \( vs : \in mS \). MS by a deterministic assignment using a function \( sf \) that describes engine acceleration and deceleration,

\[
\text{event chvs refines chvs} \quad \triangleq \quad \text{begin } vs := sf(va \to vs) \text{ end .}
\]

Field \( va \) of interface csa is instantiated as the difference between two fields \( vap \) and \( van \) in en4. The two fields model acceleration and deceleration explicitly by non-negative values. It is easy to verify that the new representation of the vehicle acceleration is unique. This is the corresponding interface instantiation:

\[
\text{interface psa instantiates csa with } va = vap-van \\
\text{fields } vs, vap, van \\
\text{constraints } vap \in 0..MA \land van \in 0..-mA \land 0 \in \{vap, van\} .
\]

Event chvs needs to be refined in en4. The simplest refinement possible is obtained by replacing \( va \) by the difference \( vap-van \):

\[
\text{event chvs refines chvs} \quad \triangleq \quad \text{begin } vs := sf(vap-van \to vs) \text{ end .}
\]

The two machines en4 and cr4 have different interfaces and cannot be composed. Both are instantiated in one more development step so that their interfaces coincide again and they are composable. The method of instantiation permits to apply instantiations in different orders or instantiate fields the same interface in different orders. Both approaches are based on the same theory. In this case study we have used the more explicit way of applying interfaces in different orders. It could easily be recasted into the second form of instantiation by combing the two interfaces asi and asa.

5. Correctness

We have used the Rodin tool \([3]\) to verify the correctness of interface refinement. First we present a technique for verifying extensions of Event-B. We believe that it is useful beyond the use in this article for verifying the correctness of interface instantiation.

5.1. A technique for proving correctness of Event-B extensions

The general idea is to encode a generic model using the Rodin tool, and illustrating the extended method using the generic model. Typically, the correctness of an extension can be stated as follows: assume the consistency of some input model, then prove the consistency of the extended output model. The approach is illustrated in Fig. 9 and contains four steps as follows.

1. Encode the generic input model.
2. Encode the generic output model.
3. Gather the consistency conditions of the input model. The consistency of a model is described by the associated proof obligations. To turn them into assumptions, we make these proof obligations axioms.

4. Prove the consistency of the output model using these axioms.

To illustrate the approach, we prove that restricted superposition refinement preserves invariance. Our input model is an abstract machine $M$ and its refinement $N$ as illustrated in Fig. 10. Variables $x$ is retained through the (superposition) refinement. Abstract event $e$ and concrete event $f$ have the same parameters $u$. Our output model is a flattened copy of $N$ (without the $\text{refines}$ clause) with an additional invariant $I(x)$.

To encode the generic machine $M$, we first model the type of variables $x$ and parameters $u$ using some carrier sets $X$ and $U$. Subsequently, $I$, $E$ and $P$ can be declared as constants with appropriate type, i.e. $I \in \mathbb{P}(X)$, $E \in \mathbb{P}(U \times X)$, and $P \in \mathbb{P}(U \times X \times X)$ as illustrated with context $M_{\text{ctx}}$ in Fig. 11. The machine $M$ is encoded accordingly using the above context, where predicates are translated.
using the set membership operator \((\in)\). For example, the invariant \(I(x)\) is translated to \(x \in I\). The encoded machine \(M_{mch}\) is in Fig. 11. Other machines are encoded in Rodin similarly.

We assume that the input machines \(M\) and \(N\) have been proved, including the proof obligation stating that event \(e\) maintains invariant \(I(x)\). To turn it into an assumption, we encode the obligation, i.e.,

\[
I(x) \land E(u, x) \land P(u, x, x') \Rightarrow I(x')
\]

as axiom \(e/INV\) in the extended context \(M_{po}\) (Fig. 12).

Similarly, the fact that \(f\) is a correct refinement of \(e\) is captured by the guard strengthening and simulation proof obligations which are encoded as the following axioms:

\[
\forall u, x \cdot x \in I \land u \mapsto x \in E \Rightarrow x \in E,
\]

and

\[
\forall u, x, x' \cdot x \in I \land u \mapsto x \in E \land u \mapsto x \mapsto x' \in Q \Rightarrow u \mapsto x \mapsto x' \in P.
\]

We prove the consistency of the output machine (a flattened copy of \(N\) with invariant \(I\)), from the axioms collected previously. For example, the proof

\[^3\text{This is a common technique to model predicate constants or variables in Event-B using first-order logic.}\]
obligation stating that $I$ is maintained by the concrete event $f$ is as follows:

$$x \in I \land u \rightarrow x \in F \land u \rightarrow x \rightarrow x' \in Q \Rightarrow x' \in I \ .$$  

(f/INV)

It is easy to see that f/INV is a consequence of e/INV, f/GRD and f/SIM.

5.2. Correctness of interface instantiation

Using the above proof method, we prove the correctness of interface instantiation as follows. For clarity, we present our proofs in this section in its generic form instead of its Rodin encoding.

5.2.1. The input model

The first component of our input model is a machine $M$ with variables $x_1$, $x_2$, $x_3$, and $x_4$. Furthermore, let $e_1$, $e_2$, $e_4$ and $e_4$ be events of $M$, accessing different sets of variables as follows,

$$e_1 \equiv \text{any } u_1 \text{ where } E_1(u_1, x_1) \text{ then } x_1 : | P_1(u_1, x_1, x'_1) \text{ end } ,$$

$$e_2 \equiv \text{any } u_2 \text{ where } E_2(u_2, x_1, x_2, x_3) \text{ then } x_1, x_2, x_3 : | P_2(u_2, x_1, x_2, x_3, x'_2, x'_3) \text{ end } ,$$

$$e_3 \equiv \text{any } u_3 \text{ where } E_3(u_3, x_2, x_3, x_4) \text{ then } x_2, x_3, x_4 : | P_3(u_3, x_2, x_3, x_4, x'_2, x'_3, x'_4) \text{ end } ,$$

$$e_4 \equiv \text{any } u_4 \text{ where } E_4(u_4, x_4) \text{ then } x_4 : | P(u_4, x_4, x'_4) \text{ end } .$$

We assume that the invariants of $M$ can be separated into: $I(x_1, x_2, x_3, x_4)$, $I_{123}(x_1, x_2, x_3)$, $I_{23}(x_2, x_3)$, $I_{234}(x_2, x_3, x_4)$.

Decomposition. We decompose $M$ into $M_{12}$ and $M_{34}$, sharing the interface $U$. The abstract interface $U$ encapsulates the shared variables $x_2$ and $x_3$ with invariant $I_{23}(x_2, x_3)$,

interface $U$

fields $x_2, x_3$

constraints $I_{23}(x_2, x_3)$.

Besides connecting to interface $U$, sub-machine $M_{12}$ has a private variable $x_1$ and invariant $I_{123}(x_1, x_2, x_3)$. Furthermore, original events $e_1$ and $e_2$ are copied as internal event of $M_{12}$. An external event $a_3$ is generated from the original event $e_3$ as follows:

$$a_3 \equiv \text{any } u_3, x_4 \text{ where } E_3(u_3, x_2, x_3, x_4) \text{ then } x_2, x_3 : | \exists x'_4 : P_3(u_3, x_2, x_3, x_4, x'_2, x'_3, x'_4) \text{ end } .$$

Machine $M_{34}$ has a similar structure to $M_{12}$. 

23
Interface Instantiation and Refinement. Assume that we develop $M_{12}$ and $M_{34}$, by instantiating the shared interface $U$ according to Fig. 13, where the interfaces are developed as follows.

\[
\begin{align*}
\text{interface } V_{12} & \text{ instantiates } U \text{ with } x_2 = h_2(y_2) \\
& \text{fields } y_2, x_3 \\
& \text{constraints } J_{12}(y_2, x_3), \\
\text{interface } V_{34} & \text{ instantiates } U \text{ with } x_3 = h_3(y_3) \\
& \text{fields } x_2, y_3 \\
& \text{constraints } J_{34}(x_2, y_3), \\
\text{interface } V & \text{ instantiates } V_{12} \text{ with } x_3 = h_3(y_3) \\
& \text{fields } y_2, y_3 \\
& \text{constraints } J_{23}(y_2, y_3).
\end{align*}
\]

\[\text{Figure 13: A lattice of interfaces}\]

In developing $M_{12}$, $x_2$ is first instantiated by $h_2(y_2)$ (i.e., $V_{12}$ instantiates $U$), subsequently $x_3$ is instantiated by $h_3(y_3)$ (i.e., $V$ instantiates $V_{12}$). The development of $M_{34}$ is similar, with an instantiation of $x_3$ followed by an instantiation of $x_2$. Note that this instantiation lattice satisfies the condition, mentioned earlier in Section 3, that the fields $x_2$ and $x_3$ are instantiated in distinct interfaces. Moreover, in the final interface $V$, the values given for $x_2$ and $x_3$ are consistent with the values used for instantiation in $V_{12}$ and $V_{34}$.

At the same time, $M_{12}$ and $M_{34}$ are refined into $O_{12}$ and $O_{34}$, relying on the interface instantiations. To be more precise, $M_{12}(x_1, x_2, x_3)^4$ is first refined to $N_{12}(y_1, y_2, x_3)$, relying on interface instantiation from $U$ to $V_{12}$, and refinement of private variable $x_1$ to $y_1$. The refinement relationship between $N_{12}$ and $M_{12}$ is captured by the gluing invariant $J_{123}(x_1, x_2, y_1, y_2, x_3)$. In $N_{12}$, internal event $e_1$ and $e_2$ are refined by $f_1$ and $f_2$, respectively. Furthermore, external event $a_3$ is refined equivalently (see Section 3) to $d_3$.

Subsequently, $N_{12}(y_1, y_2, x_3)$ is refined to $O_{12}(y_1, y_2, y_3)$, relying on interface instantiation from $V_{12}$ to $V$. In particular, in $O_{12}$ internal events $f_1$ and $f_2$ are refined by $g_1$ and $g_2$, respectively. Furthermore, external event $d_3$ is refined

---

$^4$We use the notation $M(v)$ to denote that $v$ are the variables of machine $M$. 

24
equivalently to c₂. Similarly, machine N₃₄(x₂, y₃, y₄) refines M₃₄(x₂, x₃, x₄) with the gluing invariant Jₐₙ₃₄(x₃, x₄, x₂, y₁, y₄). In particular, f₃ and f₄ are the refinement of internal events e₃ and e₄, respectively, and d₂ is the refinement of external event a₂. Subsequently, N₃₄(x₂, y₃, y₄) is refined by O(y₂, y₃, y₄), with internal events f₃ and f₄ refined by g₃ and g₄, and external event d₂ refined by c₂. The refinement relationships between the events are depicted in Fig. 14.

![Figure 14: Maintaining the external invariant of several sub-models](image)

5.2.2. The output model

Our output model is the composition machine O of O₁₂ and O₃₄ consists of internal events g₁, g₂ from O₁₂, and g₃ and g₄ from O₃₄. The correctness of our technique is guaranteed by proving that the composition O is a refinement of the original model M. In particular, the gluing invariants between O and M are the conjunctions of the gluing invariants that are used for refining the sub-machines M₁₂ and M₃₄, i.e., J₁₂₃, J₃₄, together with the interface instantiation, i.e., x₂ = h₂(y₂) and x₃ = h₃(y₃).

In the subsequent, we focus on extracting assumptions and proving that g₂ is a refinement of e₂. Proofs related to other events are similar and omitted here.

5.2.3. Extracting assumptions

The assumption in proving the correctness of the output model is that the input model has been fully proved, i.e., the initial machine M, the interface instantiation and refinements N₁₂, N₃₄, O₁₂, O₃₄.⁵ We focus on proving that g₂ is a refinement of e₂. Event e₂ is first refined into f₂ in N₁₂ and subsequently into g₂ in O₁₂ as follows:

- **event f₂ refines e₂**: any v₂ where \( F₂(v₂, y₁, y₂, x₃) \) then
  - \( y₁, y₂, x₃ : [ Q₂(v₂, y₁, y₂, x₃, y₁', y₂', x₃') \) end

- **event g₂ refines f₂**: any w₂ where \( G₂(w₂, y₁, y₂, y₃) \) then
  - \( y₁', y₂, y₃ : [ R₂(w₂, y₁, y₂, y₃, y₁', y₂', y₃') \) end

⁵The development is available at [http://deploy-eprints.ecs.soton.ac.uk/364/](http://deploy-eprints.ecs.soton.ac.uk/364/)
The fact that \( f_2 \) is a refinement of \( e_2 \) with invariant \( J_{123} \land x_2 = h_2(y_2) \) and \( g_2 \) is a refinement of \( f_2 \) with invariant \( x_3 = h_3(y_3) \) is captured by the following conditions.

\[
I_{123}(x_1, x_2, x_3) \land I_{23}(x_2, x_3) \land J_{123}(x_1, x_2, y_1, y_2, x_3) \land \\
F_2(y_2, y_1, x_2, x_3) \land Q_2(y_2, y_1, x_2, x_3, y_1', x_2') \\
\Rightarrow (\exists u_2, x_2', x_2'') \cdot \\
E_2(u_2, x_1, x_2, x_3) \land P_2(u_2, x_1, x_2, x_3, x_2', x_2'') \land \\
J_{123}(x_2', x_2'', y_1', y_2', x_2'') \land x_2'' = h_2(y_2') \quad (FE2)
\]

\[
I_{123}(x_1, x_2, x_3) \land I_{23}(x_2, x_3) \land J_{123}(x_1, x_2, y_1, y_2, x_3) \land \\
x_3 = h_3(y_3) \land \\
G_2(y_2, y_1, x_2, y_3) \land R_2(y_2, y_1, y_2, y_3, y_1', y_2') \\
\Rightarrow (\exists v_2, x_3') \cdot \\
F_2(v_2, y_2, y_1, x_2, x_3) \land Q_2(v_2, y_2, y_1, x_2, y_1', x_3') \land \\
x_3' = h_3(y_3') \quad (GF2)
\]

On the other hand, the key aspect for the correctness of our approach is that external events are refined equivalently. To be more precise, \( e_2 \) is projected as \( a_2 \) in \( M_{34} \) and is subsequently refined equivalently into \( d_2 \) in \( N_{34} \).

\[
\begin{align*}
\text{event } a_2 & \equiv \text{ any } u_2, x_1 \text{ where } E_2(u_2, x_1, x_2, x_3) \text{ then } \\
x_2, x_3 : \exists x_2', P_2(u_2, x_1, x_2, x_3, x_2', x_3') \\
\text{end,}
\end{align*}
\]

\[
\begin{align*}
\text{event } d_2 \text{ refines } a_2 & \equiv \text{ any } t_2 \text{ where } D_2(t_2, x_2, y_3, y_4) \text{ then } \\
x_2, y_3 : \exists x_2', O_2(t_2, x_2, y_3, x_2', y_3') \\
\text{end.}
\end{align*}
\]

The fact that \( a_2 \) is a refinement of \( d_2 \) ("equivalently" refined) is captured by the following condition

\[
I_{23}(x_2, x_3) \land I_{234}(x_2, x_3, x_4) \land J_{234}(x_2, x_3, x_4, y_3, y_4) \land \\
x_3 = h_3(y_3) \land \\
E_2(\exists y_2', P_2(u_2, x_1, x_2, x_3, x_2', x_3')) \\
\Rightarrow (\exists y_2', x_2') \cdot \\
D_2(t_2, x_2, y_3, y_4) \land O_2(t_2, x_2, y_3, x_2', y_3') \land \\
J_{234}(x_2', x_3', x_2', y_3', y_4) \land x_3' = h_3(y_3') \quad (AD2)
\]

In particular, given that \( h_3 \) is a bijection, we have \( x_3' = h_3(y_3') \) is equivalent to \( y_3' = h_3^{-1}(x_3') \), which allows us to apply the one-point rule to simplify (AD2),

\[
\begin{align*}
I_{23}(x_2, x_3) \land I_{234}(x_2, x_3, x_4) \land J_{234}(x_2, x_3, x_4, y_3, y_4) \land \\
x_3 = h_3(y_3) \land \\
E_2(\exists y_2', P_2(u_2, x_1, x_2, x_3, x_2', x_3')) \\
\Rightarrow J_{234}(x_3', x_4, x_2', h_3^{-1}(x_3'), y_4) \quad (AD2-SIMP)
\end{align*}
\]

26
5.2.4. Proving consistency

We focus on proving that \( g_2 \) is a refinement of \( e_2 \) using the gluing invariants \( J_{123}, J_{234} \) and \( x_2 = h_2(y_2) \) and \( x_3 = h_3(y_3) \), i.e.,

\[
\begin{align*}
I_{123}(x_1, x_2, x_3) \land I_{234}(x_2, x_3, x_4) \land \\
J_{123}(x_1, x_2, y_1, y_2, x_3) \land J_{234}(x_3, x_4, y_3, y_4) \land \\
x_2 = h_2(y_2) \land x_3 = h_3(y_3) \land \\
G_2(w_2, y_1, y_2, y_3) \land R_2(w_2, y_1, y_2, y_3, y'_1, y'_2, y'_3)
\end{align*}
\]  

(GE2)

Assuming \( I_{123}, I_{234}, J_{123}, J_{234}, x_2 = h_2(y_2), \) and \( x_3 = h_3(y_3) \), we prove:

\[
\begin{align*}
G_2(w_2, y_1, y_2, y_3) \land R_2(w_2, y_1, y_2, y_3, y'_1, y'_2, y'_3)
\end{align*}
\]  

(GF2)

\[
\begin{align*}
(\exists u_2, x'_1, x'_2, x'_3) \land E_2(u_2, x_1, x_2, x_3) \land P_2(u_2, x_1, x_2, x_3, x'_1, x'_2, x'_3) \land \\
J_{123}(x'_1, x'_2, y'_1, y'_2, x'_3) \land x'_2 = h_2(y'_2) \land x'_3 = h_3(y'_3)
\end{align*}
\]  

(AD2-SIMP)

Equality \( x'_3 = h_3(y'_3) \) and \( h_3 \) bijective

\[
(\exists u_2, x'_1, x'_2, x'_3) \land E_2(u_2, x_1, x_2, x_3) \land P_2(u_2, x_1, x_2, x_3, x'_1, x'_2, x'_3) \land \\
J_{123}(x'_1, x'_2, y'_1, y'_2, x'_3) \land x'_3 = h_2(y'_2) \land x'_3 = h_3(y'_3)
\]

The proof obligations presented in Section 3 are derived from the condition that external events are refined equivalently, i.e., the concrete event is a refinement of the abstract event and vice versa. The newly proposed proof obligations, i.e., witness feasibility, guard weakening, and co-simulation, are to prove that the abstract event is a refinement of the concrete event. They correspond to the standard proof obligations, i.e., witness feasibility, guard strengthening, and simulation in Event-B switching the roles of abstract and concrete machine. In particular, by making use of the same witness for proving equivalence between the abstract and concrete events, the proof obligations for invariance preservation are the same in both refinement directions.

6. Conclusion

We propose in this paper the notion of interface and interface instantiation for shared-variable decomposition in Event-B. An interface is a collection of external variables and their properties which can be shared between different sub-models after a decomposition. Interface instantiation combines instantiation of
carrier sets and constants with functional refinement of external variables. The encapsulation of external variables using interface offers us some flexibility in structuring the development using complex refinement and decomposition. In particular, we provide a practical method for refining external variables which is currently quite cumbersome [1].

The novelty of our approach is in the refinement of external events: we define additional proof obligations to ensure that the external events are refined equivalently. By contrast, in [1] equivalence is achieved by syntactical means replacing occurrences of abstract variables $v$ by concrete terms $h(w)$. The proof obligations of our approach are similar to the standard proof obligations, even using the same refinement witnesses for proving the equivalence. We have presented a general technique for proving correctness of Event-B extensions, and showed how this is used to demonstrate the soundness of our approach. We illustrated the method by an industrial case study modelling a cruise control system.

The simple schema of contexts and instantiations shown in Fig. 8 is essential for comprehensibility. When extending our approach as presented in this article one should make sure that the simplicity is preserved. Complex schemas of instantiations of decomposed models could easily become incomprehensible. A strong methodology is needed to master interface instantiation or any generalisation of it. Keeping track of the changes to interfaces becomes quickly challenging in multiply decomposed and refined models.

Finally, we are looking at extending the Rodin tool [3] to support the notion of interface and interface instantiation.
